Weaving Loom Mechanisms The basic mechanisms in any type of looms can be classified into Primary (shedding, picking & beat up), secondary and Auxiliary motions. Shedding opens the warp sheet into layers. The picking causes the shuttle carrying weft to be propelled from one end of the loom to another.

Mechanism (Weft insertion) of circular multiphase loom: □ Beat-up is achieved by a spiked wheel mounted on an antenna trailing behind the shuttle. □ The spikes pick up the trailing weft and finally press it into the cloth fell. □ The work of the temple is done by a fixed ring, which prevents early contraction of the cloth. □ The take up motion is mounted in a high position and the loom thus require a lofty room or space on two floors, one above the other.

Basic Weaving Mechanism: As defined earlier, the weaving process requires interlacing of warp and weft yarns at right angle to each other. In order to interlace these yarns, basic mechanism involves primary and secondary motions.

Textile - Textile - Modern looms: Modern looms still weave by repeating in sequence the operations of shedding, picking, and beating in, but within that framework there has been considerable development during the 20th century. Several new types of loom have come into industrial use, whereas older types have been refined and their scope extended.

Auxiliary Mechanism To get high productivity & good quality of fabric, additional mechanisms, called “Auxiliary mechanisms” are added to a plain power loom. The auxiliary mechanisms are useful but not absolutely essential. The auxiliary motions consist of the warp stop motion, weft stop motion and warp protector motion.

The rigid rapier is a metal or composite bar usually with a circular cross section. The rapier enters the shed from one side, picks up the tip of the filling yarn on the other side and passes it across the loom width while retracting. Therefore, a single rapier carries the yarn in one way only and half of the rapier movement is wasted.

In 1905, Sakichi invented the Toyota power loom, 1905 type, equipped with the improved warp let-off mechanism. The loom also had a sturdy structure, built of wood and steel. This was followed in 1906 by an improved version called the Toyota power loom, 1906 type. The 1906 type greatly improved efficiency and fabric quality.

The picking mechanism is provided with two torsion bars. One torsion bar is stressed in order to accelerate a gripper projectile of the loom. The second torsion bar, upon release of the first torsion bar, is temporarily connected to the first torsion bar so that energy can be stored by the second torsion bar via a double-arm lever.

Jacquard loom, also called Jacquard Attachment, or Jacquard Mechanism, in weaving, device incorporated in special looms to control individual warp yarns. It enabled looms to produce fabrics having intricate woven patterns such as tapestry , brocade , and damask , and it has also been adapted to the production of patterned knitted fabrics.
