CONTINUOUS ULTRASOUND-GUIDED AXILLARY BLOCK The indwelling axillary catheter is a useful technique for analgesia and sympathetic block. The goal of the continuous axillary block is to place the catheter within the vicinity of the branches of the brachial plexus (ie, within the "sheath" of the brachial plexus).

If all nerves cannot be seen initially, a regional approach to the ultrasound guided axillary block has been described. For this approach, the most common locations for the nerves are targeted. [5] The region of the median nerve (location 1) is blocked first, attempting to separate the median nerve from the artery.

Ultrasound guided axillary block is considered a BASIC skill level block because this is a superficial block. Insert a 5 cm 22 G insulated needle parallel to the long axis of the transducer inline with the ultrasound beam as seen in picture below. Observe the transverse view of the terminal branches on the ultrasound monitor.

USRA - Axillary Block

The Axillary nerve travels through the quadrangular space adjacent to the posterior circumflex humeral artery where it can be well visualized for blockade. A perfect indication for axillary nerve block is the injection drug use caused deltoid abscess commonly seen in emergency departments. Big abscesses may extend into the border innervations.

How to: Ultrasound-Guided Axillary Block

For all peripheral nerve blocks, a high frequency linear array ultrasound (9-18 MHz) is used. Peripheral nerves have a variable sonographic echotexture that is affected by the surrounding tissue. Classically, nerve fascicles itself appear hypochoic embedded within a more hyperechoic and homogenous perineurium and endoneurium.
